# **Exact Consensus Controllability of Multi-agent Linear Systems**

M. ISABEL GARCÍA-PLANAS Universitat Politècnica de Catalunya Departament de Matèmatiques Minería 1, Esc. C, 1-3, 08038 Barcelona SPAIN maria.isabel.garcia@upc.edu

*Abstract:* In this paper we study the exact controllability of multi-agent linear systems, in which all agents have an identical linear dynamic mode that can be in any order.

Key-Words: Multi-agent systems, consensus, controllability, exact consensus controllability.

### **1** Introduction

In the last years, the study of dynamic control multiagents systems have attracted considerable interest, because they arise in a great number of engineering situations as for example in distributed control and coordination of networks consisting of multiple autonomous agents. There are many publications as for example ([4], [10], [12], [14]). It is due to the multiagents appear in different fields as for example in consensus problem of communication networks ([10]), or formation control of mobile robots ([2]).

The consensus problem has been studied under different points of view, for example Jinhuan Wang, Daizhan Cheng and Xiaoming Hu in [12], analyze the case of multiagent systems in which all agents have an identical stable linear dynamics system, M.I. García-Planas in [4], generalize this result to the case where the dynamic of the agents are controllable.

Controllability is a fundamental topic in dynamic systems and it is studied under different approaches (see [1],[3],[7], for example). Given a linear system  $\dot{x} = Ax$ , there are many possible control matrices B making the system  $\dot{x} = Ax + Bu$  controllable. The goal is to find the set of all possible matrices B, having the minimum number of columns corresponding to the minimum number  $n_D(A)$  of independent controllers required to control the whole network. This minimum number is called exact controllability, that in a more formal manner is defined as follows.

**Definition 1** Let A be a matrix. The exact controllability  $n_D(A)$  is the minimum of the rank of all possible matrices B making the system  $\dot{x} = Ax + Bu$  controllable.

$$\begin{split} n_D(A) &= \\ \min \left\{ \mathrm{rank}\, B, \forall B \in M_{n \times i} \, 1 \leq i \leq n \mid \\ (A,B) \text{ controllable} \right\}. \end{split}$$

In this paper, we investigate the exact controllability of a class of multiagent systems consisting of k agents with dynamics

$$\dot{x}^{1} = Ax^{1} + Bu^{1}$$

$$\vdots$$

$$\dot{x}^{k} = Ax^{k} + Bu^{k}$$

where  $A \in M_n(\mathbb{C})$ , and B an unknown matrix having n rows and an indeterminate number  $1 \leq \ell \leq n$  of columns.

For this study, we need to introduce some basic concepts on Graph theory and matritial algebra.

We consider a graph  $\mathcal{G} = (\mathcal{V}, \mathcal{E})$  of order k with the set of vertices  $\mathcal{V} = \{1, \dots, k\}$  and the set of edges  $\mathcal{E} = \{(i, j) \mid i, j \in \mathcal{V}\} \subset \mathcal{V} \times \mathcal{V}.$ 

Given an edge (i, j) *i* is called the parent node and *j* is called the child node and *j* is in the neighbor of *i*, concretely we define the neighbor of *i* and we denote it by  $\mathcal{N}_i$  to the set  $\mathcal{N}_i = \{j \in \mathcal{V} \mid (i, j) \in \mathcal{E}\}.$ 

The graph is called undirected if verifies that  $(i, j) \in \mathcal{E}$  if and only if  $(j, i) \in \mathcal{E}$ . The graph is called connected if there exists a path between any two vertices, otherwise is called disconnected.

Associated to the graph we consider a matrix  $G = (g_{ij})$  called (unweighted) adjacency matrix defined as follows  $g_{ii} = 0$ ,  $g_{ij} = 1$  if  $(i, j) \in \mathcal{E}$ , and  $g_{ij} = 0$  otherwise.

In a more general case we can consider that a weighted adjacency matrix is  $G = (g_{ij})$  with  $g_{ii} = 0$ ,  $g_{ij} > 0$  if  $(i, j) \in \mathcal{E}$ , and  $g_{ij} = 0$  otherwise). The Laplacian matrix of the graph is

$$\mathcal{L} = (l_{ij}) = \begin{cases} |\mathcal{N}_i| & \text{if } i = j \\ -1 & \text{if } j \in \mathcal{N}_i \\ 0 & \text{otherwise} \end{cases}$$

**Remark 2** *i) If the graph is undirected then the* 

matrix  $\mathcal{L}$  is symmetric, then there exist an orthogonal matrix P such that  $P\mathcal{L}P^t = \mathcal{D}$ .

- ii) If the graph is undirected then 0 is an eigenvalue of  $\mathcal{L}$  and  $\mathbf{1}_k = (1, \ldots, 1)^t$  is the associated eigenvector.
- *iii) If the graph is undirected and connected the eigenvalue 0 is simple.*

For more details about graph theory see (D. West, 2007).

With respect Kronecker product, remember that  $A = (a_{ij}) \in M_{n \times m}(\mathbb{C})$  and  $B = (b_{ij}) \in M_{p \times q}(\mathbb{C})$  the Kronecker product is defined as follows.

**Definition 3** Let  $A = (a_j^i) \in M_{n \times m}(\mathbb{C})$  and  $B \in M_{p \times q}(\mathbb{C})$  be two matrices, the Kronecker product of A and B, write  $A \otimes B$ , is the matrix

$$A \otimes B = \begin{pmatrix} a_1^1 B & a_2^1 B & \dots & a_m^1 B \\ a_1^2 B & a_2^2 B & \dots & a_m^2 B \\ \vdots & \vdots & & \vdots \\ a_1^n B & a_2^n B & \dots & a_m^n B \end{pmatrix} \in M_{np \times mq}(\mathbb{C})$$

Among the properties that verifies the product of Kronecker we will make use of the following

- 1)  $(A+B) \otimes C = (A \otimes C) + (B \otimes C)$
- 2)  $A \otimes (B + C) = (A \otimes B) + (A \otimes C)$
- 3)  $(A \otimes B) \otimes C = A \otimes (B \otimes C)$
- 4) If  $A \in Gl(n;\mathbb{C})$  and  $B \in Gl(p;\mathbb{C})$ , then  $A \otimes B \in Gl(np;\mathbb{C})$  and  $(A \otimes B)^{-1} = A^{-1} \otimes B^{-1}$
- 5) If the products AC and BD are possible, then  $(A \otimes B)(C \otimes D) = (AC) \otimes (BD)$

See [9] for more information and properties. Given a square matrix  $A \in M_n(\mathbb{C})$ , it can be reduced to a canonical reduced form (Jordan form):

$$J = \begin{pmatrix} J(\lambda_1) & & \\ & \ddots & \\ & & J(\lambda_r) \end{pmatrix}, \ J(\lambda_i) = \begin{pmatrix} J_1(\lambda_i) & & \\ & \ddots & \\ & & J_{n_i}(\lambda_i) \end{pmatrix},$$
$$J_j(\lambda_i) = \begin{pmatrix} \lambda_i & & \\ 1 & \lambda_i & & \\ & \ddots & \ddots & \\ & & 1 & \lambda_i \end{pmatrix}.$$
(1)

See [5] for more information and properties.

## 2 Consensus

The consensus problem can be introduced as a collection of processes such that each process starts with an initial value, where each one is supposed to output the same value and there is a validity condition that relates outputs to inputs. It is a canonical problem that appears in the coordination of multi-agent systems. The objective is that Given initial values (scalar or vector) of agents, establish conditions under which through local interactions and computations, agents asymptotically agree upon a common value, that is to say: to reach a consensus.

The dynamic of each agent defining the system considered, is given by the following manner.

$$\dot{x}^{1} = Ax^{1} + Bu^{1}$$

$$\vdots$$

$$\dot{x}^{k} = Ax^{k} + Bu^{k}$$
(2)

 $x^i \in \mathbb{R}^n, u^i \in \mathbb{R}^\ell, 1 \leq i \leq k$ . Where matrices  $A \in M_n(\mathbb{R})$  and  $B \in M_{n \times \ell}(\mathbb{R}), 1 \leq \ell \leq n$ .

The communication topology among agents is defined by means the undirected graph  $\mathcal{G}$  with

- i) Vertex set:  $\mathcal{V} = \{1, \dots, k\}$
- ii) Edge set:  $\mathcal{E} = \{(i, j) \mid i, j \in \mathcal{V}\} \subset \mathcal{V} \times \mathcal{V}.$

an in a more specific form, we have the following definition.

**Definition 4** *Consider the system 2. We say that the consensus is achieved using local information if there exists a state feedback* 

$$u^{i} = K_{i} \sum_{j \in \mathcal{N}_{i}} (x^{i} - x^{j}), \ 1 \le i \le k$$

such that

$$\lim_{t \to \infty} \|x^i - x^j\| = 0, \ 1 \le i, j \le k.$$

$$z^{i} = \sum_{j \in \mathcal{N}_{i}} (x^{i} - x^{j}), \ 1 \leq i \leq k.$$
  
$$\dot{\mathcal{X}} = (I_{k} \otimes A)\mathcal{X} + (I_{k} \otimes B)\mathcal{U}$$
  
$$\mathcal{Z} = (\mathcal{L} \otimes I)\mathcal{X}$$
  
$$\mathcal{U} = (I_{k} \otimes K)\mathcal{Z}$$

Then, and taking into account that

$$(I_k \otimes B)(I_k \otimes K)(\mathcal{L} \otimes I_n)\mathcal{X} = (\mathcal{L} \otimes BK)\mathcal{X} = (\mathcal{L} \otimes B)(I_k \otimes K)\mathcal{X}$$

The system is equivalent to

$$\dot{\mathcal{X}} = (I_k \otimes A)\mathcal{X} + (\mathcal{L} \otimes B)\bar{\mathcal{U}} \bar{\mathcal{U}} = (I_k \otimes K)\mathcal{X}$$
(3)

## 3 Exact Consensus Controllability

We are interested in study the exact controllability of the obtained system 3. In our particular setup

**Definition 5** Let A be a matrix. The exact controllability  $n_D(I_k \otimes A)$  is the minimum of the rank of all possible matrices B making the system 3 controllable.

> $n_D(I_k \otimes A) =$  $\min \{ \operatorname{rank} B, \forall B \in M_{n \times i} \ 1 \le i \le n \mid \\ (I_k \otimes A, \mathcal{L} \otimes B) \text{ controllable} \}.$

The controllability character can be analyzed using the Hautus criteria

**Proposition 6** *The system is controllable if and only if* 

rank 
$$(sI_{nk} - (I_k \otimes A) \quad \mathcal{L} \otimes B) = kn$$

The controllability condition depends directly on the structure of the matrix L.

**Proposition 7** Let J be the Jordan reduced of the matrix  $\mathcal{L}$  and P such that  $\mathcal{L} = P^{-1}JP$ . Then, the system 3 is controllable if and only if

rank 
$$(sI_{nk} - (I_k \otimes A) \quad J \otimes B) = kn$$

**Proof.** Suppose that there exist S such that  $P^{-1}JP = \mathcal{L}$  and

$$\operatorname{rank} \begin{pmatrix} sI_{kn} - (I_k \otimes A) & \mathcal{L} \otimes B \end{pmatrix} = \\\operatorname{rank} \begin{pmatrix} P^{-1} \otimes I_n \end{pmatrix} \begin{pmatrix} sI_k \otimes I_n \end{pmatrix} - (I_k \otimes A) & J \otimes B \end{pmatrix} \\ \begin{pmatrix} P \otimes I_n \\ & P \otimes I_n \end{pmatrix} = \\\operatorname{rank} \begin{pmatrix} sI_{kn} - (I_k \otimes A) & J \otimes B \end{pmatrix}$$

**Corollary 8** Suppose that the matrix  $\mathcal{L}$  can be reduced to the Jordan form (1), with non-zero eigenvalues  $\lambda_1, \ldots, \lambda_r$ . Then, the system 3 is controllable if and only if each agent is controllable.

**Proof.** Let  $\lambda_i \neq 0, i = 1, \dots r$  be the eigenvalues of  $\mathcal{L}$ .

$$\operatorname{rank} \begin{pmatrix} s(I_{k_{ij}} \otimes I_n) - (I_{k_{ij}} \otimes A) & J_j(\lambda_i) \otimes B \end{pmatrix} = \\ \operatorname{rank} \begin{pmatrix} sI_n - A & & \lambda_i B \\ & SI_n - A & & B & \lambda_i B \end{pmatrix} \\ \operatorname{rank} \begin{pmatrix} sI_n - A & & B \\ & SI_n - A & & B \\ & & SI_n - A & & B \end{pmatrix} = \\ \operatorname{rank} \begin{pmatrix} sI_n - A & & B \\ & SI_n - A & & B \\ & & SI_n - A & & B \end{pmatrix} = \\ k \cdot \operatorname{rank} \begin{pmatrix} sI_n - A & B \\ & SI_n - A & B \end{pmatrix}$$

with 
$$k_1 + \ldots + k_r = k, \, k_{i_1} + \ldots + k_{i_{n_i}} = k_i.$$

**Corollary 9** A necessary condition for controllability of the system 3 is that the matrix  $\mathcal{L}$  has full rank.

**Example** We consider 3 identical agents with the following dynamics of each agent

$$\dot{x}^{1} = Ax^{1} + Bu^{1} 
\dot{x}^{2} = Ax^{2} + Bu^{2} 
\dot{x}^{3} = Ax^{3} + Bu^{3}$$
(4)

with 
$$A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$$
 and  $B \in M_{2 \times \ell}(\mathbb{C}), 1 \le 2$ .

The communication topology is defined by the undirected graph  $(\mathcal{V}, \mathcal{E})$ :

$$\mathcal{V} = \{1, 2, 3\}$$
  
$$\mathcal{E} = \{(i, j) \mid i, j \in \mathcal{V}\} = \{(1, 2), (1, 3)\} \subset \mathcal{V} \times \mathcal{V}$$
  
and the adjacency matrix:

$$G = \left(\begin{array}{rrr} 0 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{array}\right)$$

The neighbors of the parent nodes are  $\mathcal{N}_1 = \{2,3\}, \mathcal{N}_2 = \{1\}, \mathcal{N}_3 = \{1\}.$ 

The Laplacian matrix of the graph is

$$\mathcal{L} = \begin{pmatrix} 2 & -1 & -1 \\ -1 & 1 & 0 \\ -1 & 0 & 1 \end{pmatrix}$$

with eigenvalues  $\lambda_1 = 0, \lambda_2 = 1, \lambda_3 = 3$ .

$$\operatorname{rank} \begin{pmatrix} sI_6 - (I \otimes A) & \mathcal{L} \otimes B \end{pmatrix} = \\ \operatorname{rank} \begin{pmatrix} s & -1 & 0 & 0 & 0 & 0 & 2a & 2c & -a & -c & -a & -c \\ 0 & s & 0 & 0 & 0 & 0 & 2b & 2d & -b & -d & -b & -d \\ 0 & 0 & s & -1 & 0 & 0 & -a & -c & a & c & 0 & 0 \\ 0 & 0 & 0 & s & 0 & 0 & -b & -d & b & d & 0 & 0 \\ 0 & 0 & 0 & 0 & s & s & -1 & -a & -c & 0 & 0 & a & c \\ 0 & 0 & 0 & 0 & 0 & s & -b & -d & 0 & 0 & b & d \end{pmatrix} \\ = \begin{cases} 6 \text{ for all } s \neq 0 \\ 5 \text{ for } s = 0 \end{cases}$$

In fact, for all matrix  $B \in M_{2 \times \ell}(\mathbb{C})$  for all  $\ell \ge 0$ 

rank 
$$(sI_6 - (I \otimes A) \quad \mathcal{L} \otimes B) =$$
  
 $\begin{cases} 6 \text{ for all } s \neq 0 \\ 5 \text{ for } s = 0 \end{cases}$ 

If the matrix  $\mathcal{L}$  has full rank, then the number of columns for exact controllability of matrix  $I_k \otimes A$  depends on the multiplicity of the eigenvalues of the matrix A and we have the following result.

**Proposition 10** Let  $\mathcal{L}$  be the Laplacian matrix of a graph having full rank. Then, the exact controllability  $n_D(I_k \otimes A)$  for the system  $\dot{\mathcal{X}} = (I_k \otimes A)\mathbf{X} + (\mathcal{L} \otimes B)\overline{\mathcal{U}}$  coincides with the exact controllability  $n_D(A)$  for the system  $\dot{x} = Ax + Bu$ .

**Example** We consider 3 identical agents with the following dynamics of each agent

$$\dot{x}^{1} = Ax^{1} + Bu^{1} 
\dot{x}^{2} = Ax^{2} + Bu^{2} 
\dot{x}^{3} = Ax^{3} + Bu^{3}$$
(5)

with  $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$  and  $B \in M_{2 \times \ell}(\mathbb{C}), 1 \le 2$ .

The communication topology is defined by the undirected graph  $(\mathcal{V}, \mathcal{E})$ :

 $\mathcal{V} = \{1, 2, 3\}$ 

 $\mathcal{E} = \{(i,j) | i,j \in \mathcal{V}\} = \{(1,1), (1,2), (2,1), (2,3), (3,1)\} \subset \mathcal{V} \times \mathcal{V}$ and the adjacency matrix:

 $G = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}$ 

The neighbors of the parent nodes are  $\mathcal{N}_1 = \{1, 2\}, \mathcal{N}_2 = \{1, 3\}, \mathcal{N}_3 = \{1\}.$ 

The Laplacian matrix of the graph is

$$\mathcal{L} = \left( \begin{array}{rrr} 2 & -1 & 0 \\ -1 & 2 & -1 \\ -1 & 0 & 1 \end{array} \right)$$

with eigenvalues  $\lambda_1 = 0.3820, \lambda_2 = 2, \lambda_3 = 2.6180.$ 

	(s	-1	0	0	0	0	2a	-a	0 \
rank	0	s	0	0	0	0	2b	-b	0
	0	0	s	-1	0	0	-a	2a	-a
	0	0	0	s	0	0	-b	2b	-b
	0	0	0	0	s	-1	-a	0	a
	$\setminus 0$	0	0	0	0	s	-b	0	b /
$C$ for all s and $k \neq 0$									

6 for all s and  $b \neq 0$ .

Obviously the system  $\dot{x} = Ax + Bu$  with  $B = \begin{pmatrix} a \\ b \end{pmatrix}$  and  $b \neq 0$ .

## 4 Conclusions

In this paper, the exact controllability for multi-agent systems where all agents have an identical linear dynamic mode are analyzed.
