Abstract: The author proposes two sets of closed analytic functions for the approximate calculus of the complete elliptic integrals of the first and second kinds in the normal form due to Legendre, the respective expressions having a remarkable simplicity and accuracy. The special usefulness of the proposed formulas consists in that they allow performing the analytic study of variation of the functions in which they appear, by using the derivatives. Comparative tables including the approximate values obtained by applying the two sets of formulas and the exact values, reproduced from special functions tables are given (all versus the respective elliptic integrals modulus, $k = \sin \theta$). It is to be noticed that both sets of approximate formulas are given neither by spline nor by regression functions, but by asymptotic expansions, the identity with the exact functions being accomplished for the left end $k = 0$ ($\theta = 0^\circ$) of the domain. As one can see, the second set of functions, although something more intricate, gives more accurate values than the first one and extends itself more closely to the right end $k = 1$ ($\theta = 90^\circ$) of the domain. For reasons of accuracy, it is recommended to use the first set until $\theta = 70.5$ only, and if it is necessary a better accuracy or a greater upper limit of the validity domain, to use the second set, but on no account beyond $\theta = 88.2$.

1. Introduction - Definitions

There are many interesting domains of the pure and applied mathematics in which appear one or both complete elliptic integrals of the first and second kinds in the normal form due to Legendre. So, in the dynamics of a constrained heavy particle, the period of oscillations in a vacuum of the simple pendulum is given by a complete elliptic integral of the first kind. In the geometry of plane curves, the length of an ellipse is given by a complete elliptic integral of the second kind. In the supersonic aerodynamics, the lift coefficient of a thin delta wing having subsonic leading edges is also given by a complete elliptic integral of the second kind. The following well-known relations define all these integrals. For the first kind complete integral we have

$$K(k) = \int_0^{\pi/2} \frac{d\varphi}{\sqrt{1-k^2 \sin^2 \varphi}} = \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-k^2 t^2)}},$$

and for the second kind one

$$E(k) = \int_0^{\pi/2} \sqrt{1-k^2 \sin^2 \varphi} d\varphi = \int_0^1 \sqrt{\frac{1-k^2 t^2}{1-t^2}} dt,$$

where $k = \sin \theta$ is called *modulus*. They are calculated by expanding the integrands into series, integrating term-by-term and presented versus the modulus k or frequently versus the angle θ in some mathematical tables [1 – 6]. The values given in these tables allow performing the calculus for a given case (point), but not the analytic study of variation of the functions in which these integrals appear, by using the derivatives. In the following chapter are proposed two sets of closed analytic functions for the approximate calculus of both complete elliptic integrals. The first set is affected by the subscript 0, while the second one by the subscript 1.

2. The two sets of proposed closed analytic formulas

Using the *complementary modulus* too, $k' = \sqrt{1-k^2} = \cos \theta$,

$$K_0(k) = \frac{\pi}{\sqrt[4]{1-k^2}} \left(1 - \frac{1}{2\sqrt{2}} \frac{1+\sqrt{1-k^2}}{\sqrt[4]{1-k^2}} \right) = \pi \left(\frac{1}{\sqrt{k'}} - \frac{1}{2\sqrt{2}} \frac{\sqrt{1+k'}}{k'^{3/4}} \right), \text{ or}$$

$$K_0(\theta) = \frac{\pi}{\sqrt{\cos \theta}} \left(1 - \frac{1}{2} \frac{\cos \frac{\theta}{2}}{\sqrt[4]{\cos \theta}} \right) = \pi \left(\frac{1}{\sqrt{\cos \theta}} - \frac{1}{2} \frac{\cos \frac{\theta}{2}}{\cos^{3/4} \theta} \right);$$

$$E_0(k) = \frac{\pi}{4} \sqrt[4]{1-k^2} \left(\frac{3}{2} \frac{1+\sqrt{1-k^2}}{\sqrt[4]{1-k^2}} - 1 \right) = \frac{\pi}{4} \left[\frac{3}{2} (1+k') - \sqrt{k'} \right], \text{ or}$$

$$E_0(\theta) = \frac{\pi}{4} \sqrt{\cos \theta} \left(3 \frac{\cos^2 \frac{\theta}{2}}{\sqrt{\cos \theta}} - 1 \right) = \frac{\pi}{4} \left(3 \cos^2 \frac{\theta}{2} - \sqrt{\cos \theta} \right);$$

$$K_1(k) = \frac{\pi\sqrt{2}}{\sqrt{(1+k')\sqrt{k'}}} \left(1 - \frac{\sqrt{2}}{4} \frac{1+\sqrt{k'}}{\sqrt[4]{(1+k')\sqrt{k'}}} \right), \text{ or}$$

$$K_1(\theta) = \frac{\pi}{\cos \frac{\theta}{2} \sqrt[4]{\cos \theta}} \left(1 - \frac{1}{4} \frac{1+\sqrt{\cos \theta}}{\sqrt{\cos \frac{\theta}{2} \sqrt[4]{\cos \theta}}} \right);$$

$$E_1(k) = \frac{\pi}{4} \left[\frac{3}{2} (1+\sqrt{k'})^2 - \sqrt{2} \sqrt{1+k'} \sqrt[4]{k'} \right] - k' \cdot K_1(k), \text{ or}$$

$$E_1(\theta) = \frac{\pi}{4} \left[\frac{3}{2} (1+\sqrt{\cos \theta})^2 - 2 \cos \frac{\theta}{2} \sqrt[4]{\cos \theta} \right] - \cos \theta \cdot K_1(\theta).$$

The values strings contained in the last two columns of the previous table were canceled where each of the two closed analytic formulas proposed for the approximation of the Legendre complete elliptic integral of the first kind $K(k)$ gives too great errors for being still accepted in the usual mathematical or technical calculus. The same procedure will be applied in the case of the following table, for the same reason, concerning the accuracy of the values given by each of the other two closed analytic formulas proposed for the approximation of the Legendre complete elliptic integral of the second kind $E(k)$. The accuracy analysis of the two sets of formulas will be performed in the following chapter (no. 3). In the chapter 4 some series representations for the exact functions and for both sets of approximation, as well as for all their first order derivatives, will be given.

In the comparative tables 1 and 2, the 4D (four digit) exact values of both Legendre complete elliptic integrals reproduced from special functions tables [6], as well as their 4D approximate values obtained by applying the two sets of proposed closed analytic formulas were given (all versus the respective elliptic integrals modulus, $k = \sin \theta$). It is to be noticed that both sets of approximate formulas are not given by spline or regression functions, but by asymptotic expansions, the respective expressions having a remarkable simplicity and accuracy. The identity with the exact functions is satisfied for the left end $k = 0$ ($\theta = 0^{\circ}$) of the domain. As one can see, the second set of functions (K_1, E_1), although something more intricate, gives more accurate values than the first one (K_0, E_0) and extends itself more closely to the right end $k = 1$ ($\theta = 90^{\circ}$) of the domain.

3. The accuracy evaluation of the two sets of formulas

Let define the following relative error functions:
 $\varepsilon_{K_0}(k) = K_0(k) / K(k) - 1$; $\varepsilon_{K_1}(k) = K_1(k) / K(k) - 1$,
 for both sets of approximation of the first kind integral and
 $\varepsilon_{E_0}(k) = E_0(k) / E(k) - 1$; $\varepsilon_{E_1}(k) = E_1(k) / E(k) - 1$,
 for both sets of approximation of the second kind integral.
 Their values are given in the table 3, being expressed in thousandths (‰). These errors were calculated for the first set (K_0 and E_0) only in the field $\theta \in [54^\circ, 71^\circ]$ of the domain, with an increment of 1° , while for the second set (K_1 and E_1) only in the field $\theta \in [84^\circ.8, 88^\circ.2]$, with an increment of $0^\circ.2$, like in the above tables 1 and 2.

Table 3. Relative errors ε distribution

4. Some comparative series representations

Expanding into power series, one obtains for the complete elliptic integrals the following set of representations [5 – 7]:

$$K(k) = \frac{\pi}{2} \left(1 + \frac{1}{4}k^2 + \frac{9}{64}k^4 + \frac{25}{256}k^6 + \frac{1225}{16384}k^8 + \frac{3969}{65536}k^{10} + \frac{53361}{1048576}k^{12} + \frac{184041}{4194304}k^{14} + \frac{41409225}{1073741824}k^{16} + \dots \right);$$

$$= \frac{\pi}{2} \left\{ 1 + \sum_{n=1}^{\infty} \left[\frac{1 \cdot 3 \cdot \dots \cdot (2n-1)}{2 \cdot 4 \cdot \dots \cdot 2n} \right]^2 k^{2n} \right\} = \frac{\pi}{2} \left\{ 1 + \sum_{n=1}^{\infty} \left[\frac{(2n-1)!}{2^n n!} \right]^2 k^{2n} \right\};$$

$$E(k) = \frac{\pi}{2} \left(1 - \frac{1}{4}k^2 - \frac{3}{64}k^4 - \frac{5}{256}k^6 - \frac{175}{16384}k^8 - \frac{441}{65536}k^{10} - \frac{4851}{1048576}k^{12} - \frac{14157}{4194304}k^{14} - \frac{2760615}{1073741824}k^{16} - \dots \right);$$

$$= \frac{\pi}{2} \left\{ 1 - \sum_{n=1}^{\infty} \left[\frac{1 \cdot 3 \cdot \dots \cdot (2n-1)}{2 \cdot 4 \cdot \dots \cdot 2n} \right]^2 \frac{k^{2n}}{2n-1} \right\} = \frac{\pi}{2} \left\{ 1 - \sum_{n=1}^{\infty} \left[\frac{(2n-1)!}{2^n n!} \right]^2 \frac{k^{2n}}{2n-1} \right\}.$$

Proceeding in the same manner, we get for the first set of approximate functions (the most inaccurate) the expansions

$$K_0(k) = \frac{\pi}{2} \left(1 + \frac{1}{4}k^2 + \frac{9}{64}k^4 + \frac{25}{256}k^6 + \frac{1222}{16384}k^8 + \dots \right);$$

$$E_0(k) = \frac{\pi}{2} \left(1 - \frac{1}{4}k^2 - \frac{3}{64}k^4 - \frac{5}{256}k^6 - \frac{172}{16384}k^8 - \dots \right),$$

for the 2nd set being *practically identical with the exact ones*

$$K_1(k) = \frac{\pi}{2} \left(1 + \frac{1}{4}k^2 + \frac{9}{64}k^4 + \frac{25}{256}k^6 + \frac{1225}{16384}k^8 + \frac{3969}{65536}k^{10} + \frac{53361}{1048576}k^{12} + \frac{184041}{4194304}k^{14} + \frac{41409222}{1073741824}k^{16} + \dots \right);$$

$$E_1(k) = \frac{\pi}{2} \left(1 - \frac{1}{4}k^2 - \frac{3}{64}k^4 - \frac{5}{256}k^6 - \frac{175}{16384}k^8 - \frac{441}{65536}k^{10} - \frac{4851}{1048576}k^{12} - \frac{14157}{4194304}k^{14} - \frac{2760606}{1073741824}k^{16} - \dots \right).$$

The difference with respect to the expansions of the exact functions begins at the terms in k^8 for the first set of approximation, and at the terms in k^{16} for the second one.

For the first order derivatives of the exact functions we get

$$\frac{dK(k)}{dk} = \frac{E(k)}{k(1-k^2)} - \frac{K(k)}{k} = \frac{\pi}{4} k \left(1 + \frac{9}{8}k^2 + \frac{75}{64}k^4 + \frac{1225}{1024}k^6 + \frac{19845}{16384}k^8 + \frac{160083}{131072}k^{10} + \frac{1288287}{1048576}k^{12} + \frac{41409225}{33554432}k^{14} + \dots \right);$$

$$= \frac{\pi}{4} \sum_{n=1}^{\infty} \left[\frac{1 \cdot 3 \cdot \dots \cdot (2n-1)}{2 \cdot 4 \cdot \dots \cdot 2n} \right]^2 n k^{2n-1} = \frac{\pi}{4} \sum_{n=1}^{\infty} \left[\frac{(2n-1)!}{2^{n-1} n!} \right]^2 n k^{2n-1};$$

$$\frac{dE(k)}{dk} = \frac{E(k) - K(k)}{k} = -\frac{\pi}{4} k \left(1 + \frac{3}{8}k^2 + \frac{15}{64}k^4 + \frac{175}{1024}k^6 + \dots \right).$$

$$\begin{aligned}
& + \frac{2205}{16384}k^8 + \frac{14553}{131072}k^{10} + \frac{99099}{1048576}k^{12} + \frac{2760615}{33554432}k^{14} + \dots \Big); \\
& = -\frac{\pi}{4} \sum_{n=1}^{\infty} \left[\frac{1 \cdot 3 \cdot \dots \cdot (2n-1)}{2 \cdot 4 \cdot \dots \cdot 2n} \right]^2 \frac{nk^{2n-1}}{2n-1} = -\frac{\pi}{4} \sum_{n=1}^{\infty} \left[\frac{(2n-1)!!}{2^{n-1}n!} \right]^2 \frac{nk^{2n-1}}{2n-1}.
\end{aligned}$$

Applying the previous two exact relations and using the four definitions from chapter 2 one obtains the expansions

$$\left[\frac{dK(k)}{dk} \right]_0 = \frac{\pi}{4} k \left(1 + \frac{9}{8}k^2 + \frac{75}{64}k^4 + \frac{1225.75}{1024}k^6 + \dots \right);$$

$$\left[\frac{dE(k)}{dk} \right]_0 = -\frac{\pi}{4} k \left(1 + \frac{3}{8}k^2 + \frac{15}{64}k^4 + \frac{174.25}{1024}k^6 + \dots \right),$$

for the first set of approximate functions, and respectively

$$\begin{aligned}
\left[\frac{dK(k)}{dk} \right]_1 &= \frac{\pi}{4} k \left(1 + \frac{9}{8}k^2 + \frac{75}{64}k^4 + \frac{1225}{1024}k^6 + \frac{19845}{16384}k^8 + \right. \\
& \left. + \frac{160083}{131072}k^{10} + \frac{1288287}{1048576}k^{12} + \frac{41409226.125}{33554432}k^{14} + \dots \right);
\end{aligned}$$

$$\begin{aligned}
\left[\frac{dE(k)}{dk} \right]_1 &= -\frac{\pi}{4} k \left(1 + \frac{3}{8}k^2 + \frac{15}{64}k^4 + \frac{175}{1024}k^6 + \frac{2205}{16384}k^8 + \right. \\
& \left. + \frac{14553}{131072}k^{10} + \frac{99099}{1048576}k^{12} + \frac{2760614.25}{33554432}k^{14} + \dots \right),
\end{aligned}$$

for the second set of approximate functions.

The difference with respect to the expansions of the first order derivatives of the exact functions begins at the terms in k^7 for the first set of approximation, and at the terms in k^{15} for the second one, being much smaller than that for the expansions of the respective sets of approximate functions.

5. Graphic comparison

The variation curves of both Legendre complete elliptic integrals, as well as that of the two sets of new proposed closed analytic functions are graphically represented in the comparative figures nos. 1 and 2, all versus the angle θ , expressed in sexagesimal degrees and given by the relation $\theta = \sin^{-1}k$, k being the modulus of these elliptic integrals.

In both figures the exact functions – $K(k)$, $E(k)$ – were represented by solid (continuous) black lines, the first set of approximation – $K_0(k)$, $E_0(k)$ – by dashed black lines and the second set of approximation – $K_1(k)$, $E_1(k)$ – by solid red lines respectively.

Figure 1. Comparison of the Legendre complete elliptic integral of the first kind $K(k)$ with the new proposed closed analytic functions $K_0(k)$ and $K_1(k)$

Figure 2. Comparison of the Legendre complete elliptic integral of the second kind $E(k)$ with the new proposed closed analytic functions $E_0(k)$ and $E_1(k)$

6. Conclusion

For reasons of accuracy it is recommended in the current mathematical and technical applications, to use the first set until $\theta = 70^\circ.5$ ($k = 0.94264$) only, and if it is necessary a better accuracy or a greater upper limit of the validity domain, to use the second set, but on no account beyond $\theta = 88^\circ.2$ ($k = 0.99951$).

7. Note

Except for the comparative tables (nos. 1 and 2), the errors table becoming thus table no. 1, this work was published previously in a proceedings volume (scientific bulletin), in Romanian [8].
